

## **RISK ADJUSTMENT: A CURE FOR ADVERSE SELECTION EXECUTIVE SUMMARY**

### **Findings**

Fixed periodic per capita, or “capitated” payments by purchasers to health plans and health plans to medical groups, if not adjusted for the medical needs of different patients, gives health plans and medical groups an incentive to avoid caring for the sickest patients.

These incentives result in “adverse selection,” i.e., a competitive disadvantage for academic health centers and other providers with reputations for excellence that attract the sickest patients.

What is needed to combat the problem of adverse selection and risk avoidance is “risk adjustment,” i.e., to adjust capitation payments to compensate health plans and providers for enrolling and caring for patients with more costly medical conditions, enough to eliminate incentives for skimming and stinting.

A consensus has emerged among leading experts that good enough methods are now available and ought to be put into practice post-haste.<sup>1</sup> For a variety of important reasons, risk adjustment should begin to be implemented as quickly as possible.

Risk adjustment suffers from a collective action problem. In order for risk adjustment to change the incentives of even one large health plan, many firms, very large firms, or some large purchasing groups need to introduce it. Due to the need for critical mass, one employer acting on its own can not correct the incentives of unadjusted capitation. Public action is needed to make this vitally important change.

In addition, to encourage health plans to contract with the best providers and to encourage providers to develop expertise in treating the sickest patients, the adjusted payments must be passed through the health plans to their contracting medical groups and other providers. Adverse selection is an especially important issue for academic medical centers: since they typically have deserved reputations for being among the best and most technologically advanced, they are likely to attract the sickest patients, and therefore do not have a level playing field without risk adjustment in a competitive managed care environment.

### **Preliminary Recommendations**

The California Managed Care Improvement Task Force recognizes that risk adjustment entails some extra cost and effort initially, and despite that, endorses risk adjustment as worth the additional investment. We base this recommendation on the reasoned analysis that in the long run, risk adjustment will save society resources by reshaping

current negative incentives into a system of providing more efficient, higher quality care for all patients.

Specific actions that should be considered in California include:

- CalPERS, preferably in combination with PBGH with its nearly three million members including UC, should adopt and implement a state-of-the-art risk adjustment system. If they have not begun to do so within three years, the State of California should require it of CalPERS.
- Actions should be taken by the State of California to encourage the greater spread of pooled purchasing arrangements, capable of risk adjustment, for small and medium sized employment groups. Any new purchasing groups should be required to risk adjust payments to plans and should further require risk adjusted payments flow through to medical groups and other providers.
- The California Department of Health Services (DHS) should seek to join with the Health Care Financing Administration (HCFA, federal administrator of the Medicare and Medicaid programs) in a cooperative project to explore risk adjustment for payments to managed care plans serving Medi-Cal beneficiaries and that risk adjusted payments flow through appropriately to providers.
- Similarly, DHS should seek to participate in a HCFA-sponsored risk adjustment demonstration project for Medicare managed care.
- All major purchasers doing risk adjustment should require that the health plans pass through the adjusted payments to their contracting medical groups and clinical providers.

When the appropriate cost- benefit analyses are undertaken for implementation of the above proposals, methodology must be grounded in the goal of long-term and substantial health outcomes improvement.

## **RISK ADJUSTMENT: A CURE FOR ADVERSE SELECTION**

### **I. TODAY'S PROBLEM: ADVERSE SELECTION**

Today, payors (i.e., employers and employer groups) almost universally pay health plans the same premium for caring for a healthy young adult and for a patient with serious, costly chronic conditions. This is true even though a seriously ill patient might cost many times as much per year to care for. Typically the same thing occurs in fixed, periodic, per capita or "capitated" payments from health plans to medical groups, though there are some contracts in which the capitation payments are adjusted for age, sex, and less frequently severity.<sup>2</sup>

There is a serious problem with this practice. One might argue that the law of large numbers would cause the incidence of high cost cases among health plans to be spread evenly, so that no health plan would be likely to be injured in the competitive marketplace by unfavorable or "adverse selection" of high cost patients. This might be so if somehow patients were randomly assigned among health plans. This might also be the case if everyone purchased health insurance through their employer and all employers chose one health plan for their entire employment group, though this scenario would be undesirable because it would eliminate individual choice. However, high cost cases are definitely not spread evenly when people have choices among health plans and associated providers.

When people with chronic conditions have choices among health plans, they will naturally seek out and choose those health plans contracting with providers who are known or believed to be best at treating their costly diseases. Thus, in a competitive market, the health plans whose doctors have the best reputations for, say, treating heart disease or breast cancer or AIDS will attract the most patients with those costly conditions. Therefore, if payors pay the same amount for each enrollee, health plans will be punished with an extra cost burden for contracting with the best doctors. Or, if the one-size-fits-all capitation payments are passed through to the medical groups, the providers with the best reputations for treating costly diseases will be punished with an extra cost burden, a burden that may even threaten to drive them out of business.

In this case, a survival strategy for a medical group is to avoid developing a reputation for excellence, or (since the word is likely to get around) to avoid developing excellence itself. This is clearly an undesirable incentive. We all want a health care system that will provide the best care and technology when we or our family members become seriously ill. However, the existing standard payment methodology can work powerfully against this.

Adverse selection was not a serious problem before the era of vigorous price competition among health plans, approximately before the early 1990s. In those times, most

---

<sup>2</sup> "The Physician Group Assessment of HMO Performance, 1997", Pacific Business Group on Health reports that 68.8% of HMOs adjust capitation payments to medical groups to account for differences in patients by age and gender, but only 10.3% adjust for disease severity. The survey question does not distinguish whether HMOs adjust all or only some of their payments to physician groups.

employers and employees behaved in a cost-unconscious manner. Typically, employers paid the entire premium, whichever plan an employee chose. In such a market, healthy and sick employees were more evenly distributed among plans, and a health plan suffering unfavorable selection could always raise its rates, so was not seriously punished.

That situation is different today because increasing numbers of employers (e.g. the federal government, University of California (UC), Stanford University, and employers participating in the Pacific Business Group on Health (PBGH)) require their employees to pay the difference in premiums if they choose a more expensive plan. Given a price sensitive choice, the healthiest—those who have the least reason to care about the quality of their doctors—are likely to choose the lowest priced plans, while only the sickest are likely to be willing to pay the extra cost associated with health plans and providers that have attracted the sickest patients.

Adverse selection is an especially important issue for academic health centers (AHCs). Since they typically have deserved reputations for being among the best and most technologically advanced, they are likely to attract the sickest patients in a competitive managed care arrangement. Thus, if health plans pay unadjusted rates, AHCs will not be able to compete to provide clinical services on a level playing field. Such adverse selection is one part of the economic problem posed for AHCs by competitive managed care.

People frequently criticize health plans for employing strategies that attract healthy patients and avoid enrollment of high risk or very costly patients, commonly known as “skimming”. Critics should realize that this incentive is not the creation of the health plans; it is the consequence of payors paying health plans in such a way as to create the perverse incentive to skim. The “villains” of the story include the Federal Employees Health Benefits Program (FEHBP), Stanford, UC, the California Public Employees Retirement System (CalPERS), PBGH, and most other employers—institutions that are highly regarded and whose leaders would not deliberately create destructive incentives. That they have behaved the way they have can be explained by a lack of understanding of the implications of the recent changes in the health care system, the lack of consensus on methods for correcting the problem, the lack of data available to improve current methods, and the lack of institutions to carry out solutions. Still, the payors must reform their payment methodology if the negative incentives are to be corrected.

## **II. A SOLUTION: RISK ADJUSTMENT**

Perhaps the most cogent critique of the present version of competition was offered by the late Cardinal Bernardin, Archbishop of Chicago and leading spokesman of the Catholic Church in the United States on health policy. He said:

We must develop and adopt methods to compensate health plans that enroll disproportionate numbers of sick people at the expense of plans that enroll disproportionate numbers of healthy people. *If we do not, we will witness a morally repugnant system in which plans will compete to avoid caring for the sick, thus avoiding a central purpose of healthcare*

*altogether.* (Italics added.) These methods, known as “risk adjustment,” reduce incentives for managed care plans to compete based on enrolling only healthier populations.<sup>3</sup>

Thus it is the responsibility of purchasers, especially major purchasers with resources and market power, to reform the payment system in a way that gets the incentives right. Getting the incentives right does not mean a complete reversal from capitation. Rather, what is needed is to adjust capitation payments to compensate health plans and providers for enrolling and caring for patients with more costly medical conditions, enough to eliminate incentives for skimming.<sup>4</sup>

### **A. Methodology**

Adequately compensating health plans can be done today by “risk adjusting” premiums. In its most recent form, the risk adjustment process entails:

- gathering diagnostic information on each enrolled patient, using each health plan’s computerized data base on its patients;
- using econometric methods to convert diagnostic information into expected or average cost of care per patient per year for such a patient (i.e., the enrollees’ risk);
- adding up the expected costs for enrollees in each health plan and converting the totals into each plan’s relative risk among competing health plans;
- adding a surcharge to the premium of each plan getting favorable selection, and using the proceeds to compensate the plans that got unfavorable selection. This step is would be performed by the sponsor or central clearing house.

Risk adjustment enables health plans getting unfavorable selection to offer a lower premium in the marketplace and therefore to be competitive with plans that got favorable selection. It is important to note that for risk adjustment to achieve its purposes, the adjusted payments must be passed through the health plans to their contracting medical groups.

### **B. Adequacy of Risk Adjustment Methods**

Substantial research has been conducted on risk adjustment, but until recently there has been controversy over the adequacy of existing methods. Recently, a consensus has emerged among the leading experts—Professors Hal Luft and Joseph Newhouse among others—that good enough methods are now available and ought to be put into practice.<sup>5</sup>

So far, risk adjustment has been tried on a limited scale. From the outset of its HMO program, Medicare has used a formula that adjusts payments to HMOs based on age, sex, location, institutional and welfare status of the patients. This method has been widely criticized for not including diagnostic information. Starting in 1995, the Health Insurance Plan of California (HIPC) introduced a risk adjustment model based on

diagnostic information from hospital inpatient records, the best information available at the time.<sup>6</sup> The HIPC put its risk adjustment model into practical operation to very good effect. All concerned recognize that a better model is needed using both inpatient and outpatient information. However, the experience shows that risk adjustment is practical on a large scale.

### **C. The Time is Now for Risk Adjustment**

There are several reasons to begin to implement risk adjustment now.

- First, risk adjustment can help to correct the serious problems discussed above, that is, to get the incentives right.
- Second, risk adjustment will begin to level the playing field, in particular, by defraying the economic damage to AHCs and other providers of recognized excellence—the ones we want to be around when our family members become seriously ill.
- Third, some kinds of managed care products that offer wider access to providers naturally tend to draw unfavorable selection compared to narrow access products because the people who choose them are more likely to have health problems. Adverse selection is likely to drive these products out of the market unless there is risk adjustment to allow them to compete on a level playing field. Their demise would narrow consumer choice, weaken competition, and reduce consumer welfare.
- Fourth, risk adjustment methodology does not have to be perfect to make an impact. Arguably, some improvement is better than no improvement, the implementation of current risk adjustment methods will instill greater urgency among participants in the effort to improve them, such as by developing the information infrastructure required to produce outpatient data efficiently.
- Finally, and in a sense most fundamentally, risk adjustment is needed to inspire confidence in the moral integrity of the health care financing system.

Progress related to risk adjustment has been slow for several reasons. For one, as explained above, the problem has emerged as a serious one only quite recently. Moreover, research producing persuasive results on methods is relatively new. Beyond these reasons, with the exception of the federal government, no individual purchaser has found introduction of risk adjustment to be beneficial because there is a collective action problem. That is, one employer acting alone cannot affect the incentives of a large health plan. For risk adjustment to be effective in addressing incentives, many firms, very large firms, or some large purchasing groups need to introduce it.

Risk adjustment entails some extra cost and trouble, though modern information technology can reduce these. Moreover, risk adjustment is worth the additional cost. In the long run, risk adjustment will save society resources by redirecting the incentives of health plans from skimming to providing efficient high quality care for the most costly patients.

### III. RECOMMENDATIONS

The following steps would bring the number of Californians under risk adjustment to some six million or more. This would likely be sufficient to change incentives. Risk adjustment would benefit the purchasers involved by saving money from unnecessary windfall payments to plans experiencing favorable selection and by making it rewarding for plans to attract the sickest patients and treat them efficiently. In addition, a risk adjustment system would enable these purchasers to price more accurately the risks being covered.

- The California Department of Health Services (DHS) should seek to join with the Health Care Financing Administration (HCFA, administrator of the Medicare and Medicaid programs) in a cooperative project to do risk adjustment for payments to managed care plans serving Medi-Cal beneficiaries.
- Similarly, DHS should seek to participate in a HCFA-sponsored risk adjustment demonstration project for managed care plans serving Medicare beneficiaries as and when such demonstration projects are proposed.
- CalPERS, preferably in combination with PBGH with its nearly three million members including UC, should adopt and implement a state-of-the-art risk adjustment system. If they have not begun to do so within three years, the state should require it of CalPERS. CalPERS, in conjunction with PBGH, is best positioned to set the standard for the whole state. Once they are doing risk adjustment, it becomes much easier for others to follow.
- Beyond this, actions should be taken by the state to encourage the greater spread of pooled purchasing arrangements, capable of risk adjustment, for small and medium sized employment groups. Any new purchasing groups should be required to risk adjust payments to participating plans. (The recently started Benefits Alliance purchasing group uses risk adjustment.)
- As described above, to achieve the purpose of risk adjustment, the adjusted payments must be passed through the health plans to their contracting medical groups. Therefore, major purchasers doing risk adjustment should see to it that this is done.
